

FISH, Probe Protocol
September 2006, Updated August 20th, 2013

Filtering Samples

- 1) Seawater samples were killed with 2% paraformaldehyde or 10% formalin.
- 2) The seawater was filtered through 0.2 µM white polycarbonate membrane filter 25mm (Osmonics). Typically 10mls of BATS water or 1:100 dilution of culture with filtered seawater.
- 3) The filter is fixed to a slide with a tough spot at each end.
- 4) These can be stored at -20°C with dessicant until ready to proceed. (~2 months- 1 year).

Probing Filters

- 1) Cut the filter into quarters. Fix a quarter onto a new slide using two tough spots and label the slide with the probe, sample, tower and mls filtered.
- 2) Wash the filters in 95% Ethanol
- 3) Probe the sample with 40µl of 2ng/µl probe in hybridization solution. To dilute the probe (10ng/µl), use a 1 in 10 dilution, adding the hybridization solution first.
- 4) The hybridization solution to use depends on the probe.
- 5) Place a cover slip (22mm) on top of the two tough spots. This makes it easier to remove later and ensures most of the probe remains on top of the filter.
- 6) Place in a hybridisation oven set at 37°C for 16 hours.

Washing the Filters

- 1) Set up a water bath at required temperature check with a thermometer.
- 2) Temperature depends on the probe used.
- 3) Place two coplin jars with hybridization wash solution in the water bath.
- 4) Remove the cover slip by hand and place in the wash for 10 min.
- 5) Place in the second wash for 10 mins.

Mounting the Filters

- 1) Cut off the filter quarter from the tough spots. Dry the filters on Whatman filter paper (paper towel or kimwipe).
- 2) Remove the tough spots and clean the slide with kim wipe.
- 3) Place the filter correct side up onto the slide and cover with a coverslip (22mm) containing a drop of 20µl DAPI/citiflour (1:2) mixture. Press down to remove excess mountant and dry using a kimwipe.
- 4) Seal with nail polish and place at 4°C to reduce floaters.
